1 | Introduction

Given the opportunity to review the design document and related smart contract source code of the `WrapperFactorLeverageVault` in Factor, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

1.1 About Factor

Factor provides a middleware infrastructure to aggregate core DeFi primitives, including the creation, management, and discovery of powerful financial instruments with innovative vaults, yield pools, lending pools, liquidity pools, and tokenized baskets. The audited `WrapperFactorLeverageVault` contract wraps the leverage vault to facilitate the user position management and interaction with external strategies. The basic information of the audited protocol is as follows:

Table 1.1: Basic Information of `WrapperFactorLeverageVault`

Item	Description
Name	Factor Studio
Website	https://factor.fi/
Type	Smart Contract
Platform	Solidity
Audit Method	Whitebox
Latest Audit Report	March 28, 2024

In the following, we show the Git repository of reviewed files and the commit hash value used in this audit. Note that the repository has a number of contracts and this audit covers the following contract: `WrapperFactorLeverageVault.sol`.

1.2 About PeckShield

PeckShield Inc. [5] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (<https://t.me/peckshield>), Twitter (<http://twitter.com/peckshield>), or Email (contact@peckshield.com).

Table 1.2: Vulnerability Severity Classification

Impact	High	Medium	Low
	Critical	High	Medium
	High	Medium	Low
	Medium	Low	Low
Likelihood			

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [4]:

- Likelihood represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a checklist of items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy

Table 1.3: The Full Audit Checklist

Category	Checklist Items
Basic Coding Bugs	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy

	Frontend-Contract Integration
	Deployment Consistency
	Holistic Risk Management
Additional Recommendations	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- Semantic Consistency Checks: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [3], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functionality that processes data.
Numeric Errors	Weaknesses in this category are related to improper calculation or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like authentication, access control, confidentiality, cryptography, and privilege management. (Software security is not security software.)
Time and State	Weaknesses in this category are related to the improper management of time and state in an environment that supports simultaneous or near-simultaneous computation by multiple systems, processes, or threads.
Error Conditions, Return Values, Status Codes	Weaknesses in this category include weaknesses that occur if a function does not generate the correct return/status code, or if the application does not handle all possible return/status codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper management of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logic	Weaknesses in this category identify some of the underlying problems that commonly allow attackers to manipulate the business logic of an application. Errors in business logic can be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices that are deemed unsafe and increase the chances that an exploitable vulnerability will be present in the application. They may not directly introduce a vulnerability, but indicate the product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the `WrapperFactorLeverageVault` contract in `Factor`. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	1	
Low	1	
Informational	0	
Total	2	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in [Section 3](#).

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 low-severity vulnerability.

Table 2.1: Key WrapperFactorLeverageVault Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Improved Constructor/Initialization Logic in WrapperFactorLeverageVault	Coding Practices	Confirmed
PVE-002	Medium	Possible Reward Misadjustment With Debt Balance Manipulation	Business Logic	Resolved

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 | Detailed Results

3.1 Improved Constructor/Initialization Logic in WrapperFactorLeverageVault

- ID: PVE-001
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: WrapperFactorLeverageVault
- Category: Coding Practices [2]
- CWE subcategory: CWE-1126 [1]

Description

To facilitate possible future upgrade, the vault contract is instantiated as a proxy with actual logic contracts in the backend. While examining the related contract construction and initialization logic, we notice current constructor routine can be improved.

In the following, we shows its initialization routine. We notice its constructor does not have any payload. With that, it can be improved by adding the following statement, i.e., `_disableInitializers()`; . Note this statement is called in the logic contract where the initializer is locked. Therefore any user will not able to call the `initialize()` function in the state of the logic contract and perform any malicious activity. Note that the proxy contract state will still be able to call this function since the constructor does not effect the state of the proxy contract.

```
78     function initialize(InitParams memory initParams) public initializer {
79         __ERC20AUGMENTED_init(initParams._name, initParams._symbol);
80         __ERC721_init(initParams._name, initParams._symbol);
81         __FactorGauge_init(initParams._veFctr, initParams._gaugeController);
82         __FactorBoostReward_init(initParams._boostController, initParams._rewardDuration
            );
83
84         allowedAsset = initParams._allowedAsset;
85         allowedDebt = initParams._allowedDebt;
86         factorLeverageVaultAddress = initParams._factorLeverageVaultAddress;
```

87

}

Listing 3.1: WrapperFactorLeverageVault::initialize()

Recommendation Improve the above-mentioned constructor routine in WrapperFactorLeverageVault

Status This issue has been confirmed.

3.2 Possible Reward Misadjustment With Debt Balance Manipulation

- ID: PVE-002
- Severity: Low
- Likelihood: Low
- Impact: Low
- Target: WrapperFactorLeverageVault
- Category: Coding Practices [2]
- CWE subcategory: CWE-1126 [1]

Description

To facilitate the strategy management, the WrapperFactorLeverageVault contract has a key function `upgradeStrategy()` that allows the position owner to upgrade the strategy implementation. This is handy in case some protocols change their address or when there is a update for a bug fix. In the meantime, we notice the reward distribution may be largely affected by the debt balance returned from the strategy. Therefore, there is a need to ensure the new strategy implementation is whitelisted before the upgrade.

To elaborate, we show below the implementation of this `upgradeStrategy()` routine. This routine has a rather straightforward logic in validating the caller and then upgrading the strategy implementation. This upgrading makes it necessary to validate the given implementation is whitelisted. Meanwhile, the strategy's debt balance may be affected if the protocol allows a third-party to pay the debt for an existing borrower. In this case, there is a need for an external bot to reliably monitor the debt balance changes and timely update the position debt balance up-to-date.

```

307     function upgradeStrategy(uint256 positionId, address upgradeImplementation) public {
308         if (ownerOf(positionId) != msg.sender) revert NotOwner();
309         address positionStrategy = ILeverageVault(factorLeverageVaultAddress).positions(
            positionId);
310         IStrategyUpgradeTo(positionStrategy).upgradeTo(upgradeImplementation);
311         emit UpgradeStrategy(positionStrategy, positionId, upgradeImplementation);
312     }

```

Listing 3.2: WrapperFactorLeverageVault::upgradeStrategy()

Recommendation Revise the above routine to ensure the new strategy implementation is whitelisted.

Status The issue has been resolved as the team confirms the requirements of whitelisting the strategy implementation and having an external bot to ensure the user debt balance stays up-to-date.

4 | Conclusion

In this audit, we have analyzed the design and implementation of the `WrapperFactorLeverageVault` contract in `Factor`, which provides a middleware infrastructure to aggregate core DeFi primitives, including the creation, management, and discovery of powerful financial instruments. The audited `WrapperFactorLeverageVault` contract wraps the leverage vault to facilitate the user position management and interaction with external strategies. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and fixed

Meanwhile, we need to emphasize that [Solidity](#)-based smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
